Problem 1. Let F be a subfield of \mathbb{C} , and let K/F be a degree 2 extension. Is K/F necessarily Galois?

Solution. Yes. Since $F \subset \mathbb{C}$, HW2 problem 4 (Stewart 5.5) implies that $K = F(\sqrt{\lambda})$ for some $\lambda \in F$ (and $\sqrt{\lambda} \notin F$ by hypothesis). Thus, K is the splitting field of $x^2 - \lambda \in F[x]$.

Problem 2. Let $F \subset M \subset K$ be fields.

(a) Suppose K/F is Galois. Is K/M necessarily Galois?

Solution. Yes, by the fundamental theorem of Galois theory.

(b) Suppose K/F is Galois. Is M/F necessarily Galois?

Solution. No. Take $F = \mathbb{Q}$ and $M = \mathbb{Q}(\sqrt[3]{2})$, and let K be the splitting field of $x^3 - 2$ (so that $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$, where $\zeta_3 = \exp(2\pi i/3)$ is a third root of unity). Since K is the splitting field of an IR (by Eisenstein with p = 2) polynomial over \mathbb{C} , we know K/F is Galois. But M/F isn't Galois because $[M:F] = 3 \neq 1 = |\operatorname{Gal}(M/F)|$.

(c) Suppose M/F and K/M are both Galois. Is K/F necessarily Galois?

Solution. No. Take $F = \mathbb{Q}$, $M = \mathbb{Q}(\sqrt{2})$, and $K = \mathbb{Q}(\sqrt[4]{2})$.

Problem 3. Classify the Galois groups of the following polynomials.

(a) $f(x) := x^3 - 3x + 1$ over \mathbb{Q} .

Solution. It's irreducible by reduction modulo 2 (it's cubic, so it's reducible if and only if it has a root, which it doesn't in \mathbb{F}_2). So, a theorem from class says that the Galois group is $A_3 \cong Z_3$ if the discriminant is a square in \mathbb{Q} and S_3 otherwise. Indeed, the discriminant is 81, so the Galois group is Z_3 .

(b) The minimal polynomial of $\sqrt{2+i}$ over \mathbb{Q} .

Solution. Call this thing α . The minimal polynomial is $f(x) := x^4 - 4x^2 + 5$, which is IR; $f(x+1) = x^4 + 4x^3 + 2x^2 - 4x + 2$ is IR by Eisenstein with p=2. (Alternatively, you could reduce modulo 2, check that \overline{f} has no roots in \mathbb{F}_2 , and then conclude that it also doesn't factor into irreducible quadratics since the only such quadratic over \mathbb{F}_2 is $x^2 + x + 1$, which doesn't square to \overline{f} .)

Thus, $\mathbb{Q}(\alpha)$ has degree 4, but is it the splitting field? Well, using the quadratic formula on $f(\sqrt{x})$, we find that the roots of f are $\pm \alpha$ and $\pm \beta$, where $\beta = \sqrt{2-i}$. (In particular, the roots are all distinct, so by a problem from HW4, the form of f tells us that the Galois group is contained in D_4 .) Note that $\alpha\beta = \sqrt{5} \notin \mathbb{Q}(\alpha)$, so $\beta \notin \mathbb{Q}(\alpha)$, so the splitting field K isn't $\mathbb{Q}(\alpha)$.

But! Note that $i \in \mathbb{Q}(\alpha)$, so the minimal polynomial of β over $\mathbb{Q}(\alpha)$ is $x^2 - 2 + i$, which is a quadratic. So, by the Tower Law, $[K : \mathbb{Q}] = 8$, so the Galois group has order 8. By a problem from HW4, the form of f tells us that the Galois group is contained in D_4 , which has order 8, so the Galois group is D_4 .

(c) The minimal polynomial of $\sqrt{2+\sqrt{2}}$ over \mathbb{Q} .

Solution. Call this thing α . To find $[K:\mathbb{Q}]=|\operatorname{Gal}(K/\mathbb{Q})|$, one can compute that α is a root of x^4-4x^2+2 , which is IR over \mathbb{Q} by Eisenstein with p=2. So, $\mathbb{Q}(\alpha)$ has degree order 4.

But does K also have order 4? Well, let's find out what the roots are by using the quadratic formula on x^2-4x+2 . We get that the roots are $\pm \alpha$ and $\pm \beta$, where $\beta=\sqrt{2-\sqrt{2}}$, so $K=\mathbb{Q}(\alpha,\beta)$. By squaring α , we observe that $\mathbb{Q}(\alpha)$ contains $\sqrt{2}$. Does it also contain β ? One litmus test is to see what $\alpha\beta$ is. It's actually $\sqrt{2}$, which, sure enough, is in $\mathbb{Q}(\alpha)$. Therefore, $\mathbb{Q}(\alpha) \ni \sqrt{2}/\alpha = \beta$. Hence, $\mathbb{Q}(\alpha) = K$, so the Galois group has order 4.

So, is it $Z_2 \times Z_2$ or Z_4 ? Well, if α is sent to $-\alpha$, then $-\alpha$ is sent to α . Similarly, if β is sent to $-\beta$, then $-\beta$ is sent to β . This gives us two distinct elements of order 2 in the Galois group, so it's $Z_2 \times Z_2$ since Z_4 only has one element of order 2.

(d) $f(x) := x^4 - 2$ over F, where F is the splitting field of $x^2 - 2$ over \mathbb{Q} .

Solution. Write $F=\mathbb{Q}(\sqrt{2})$. The splitting field of f over \mathbb{Q} is $\mathbb{Q}(\sqrt[4]{2},i)=F(\sqrt[4]{2},i)$, and $\mathrm{Gal}(K/\mathbb{Q})\leq D_4$ by a problem from HW4 (look at the form of f). It follows from the Tower Law that

$$|\operatorname{Gal}(K/F)| = \frac{|\operatorname{Gal}(K/\mathbb{Q})|}{|\operatorname{Gal}(F/\mathbb{Q})|} \le \frac{8}{2} = 4,$$

so Gal(K/F) is either 1, Z_2 , Z_4 , or $Z_2 \times Z_2$.

We claim $\operatorname{Gal}(K/F) \cong Z_2 \times Z_2$. By the bound from above, it will suffice to just find two distinct elements of order 4, since that will imply that $Z_2 \times Z_2 \leq \operatorname{Gal}(K/F)$. Indeed, consider the maps $[\sqrt[4]{2} \mapsto -\sqrt[4]{2}, i \mapsto i]$ and $[\sqrt[4]{2} \mapsto \sqrt[4]{2}, i \mapsto -i]$. These are two valid automorphisms of order 2 that fix F, so we're done. (Note that $\sqrt[4]{2}$ can't be sent to $\pm i\sqrt[4]{2}$ since then $\sqrt{2} = (\sqrt[4]{2})^2$ would get sent to $(\pm i\sqrt[4]{2})^2 = -\sqrt{2}$, meaning that F wouldn't be fixed.)

Or, we can deduce that it's $Z_2 \times Z_2$ (as opposed to Z_4) by the fundamental theorem of Galois theory, since the splitting field has two distinct subextensions of degree 2 over F (which, by the fundamental theorem, correspond to two distinct subgroups of order 2 in Gal(K/F)).

(e) The same polynomial as in the last part, but now over \mathbb{Q} .

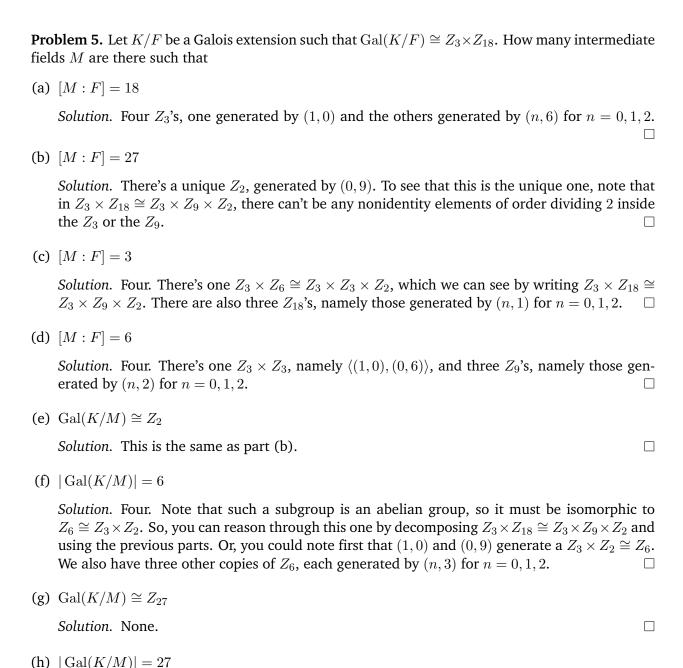

Solution. D_4 . The previous part and the Tower Law imply that $[K : \mathbb{Q}] = 8$. The only subgroup of order 8 in S_4 , thanks to Sylow II.

Problem 4. Let K be a subfield of \mathbb{R} , and let $f \in K[x]$ be an irreducible polynomial. Show that if the Galois group of f has odd order, then the discriminant of f is positive.

Solution. Let's prove the contrapositive. Note that the discriminant of f can't be 0, since then f would have a repeated root, making it inseparable and thus (by virtue of the fact that $K \subset \mathbb{C}$) reducible.

So, suppose that the discriminant of f is negative. Then, by the definition of the discriminant in terms of the roots, at least one of the roots α is nonreal; since $K \subset \mathbb{R}$, it follows that $\overline{\alpha}$ is also a (distinct) root of f. Therefore, complex conjugation is an order 2 element of f (rather than an order 1 element), so by Lagrange's theorem, the Galois group has even order.

(Note that complex conjugation is always in the Galois group of a polynomial over a real ground field—sometimes as an order 1 element, other times as an order 2 element—because complex conjugation fixes \mathbb{R} and is a field automorphism of \mathbb{C} .)

Problem 6. True or false? Justify your answer.

- (a) If $\alpha \neq \beta$ are both irrational, then $\mathbb{Q}(\alpha, \beta)$ is not a simple extension of \mathbb{Q} .
- (b) Every algebraic extension is finite.
- (c) Two extensions of the same degree are isomorphic.

Solution. Just one, generated by (1,0) and (0,2).

(d) Suppose there exist α and β such that the extensions $\mathbb{Q}(\alpha)/\mathbb{Q}$ and $\mathbb{Q}(\beta)/\mathbb{Q}$ are isomorphic. Then α and β have the same minimal polynomial over \mathbb{Q} .

Problem 7. Let K/\mathbb{Q} be a Galois extension of degree 4 and suppose that $i \in K$. Prove that $\operatorname{Gal}(K/\mathbb{Q}) \simeq Z_2 \times Z_2$. Hint: what can you say about the extension $K/\mathbb{Q}(i)$?

Problem 8. Show that there are infinitely many irreducible polynomials over any field. *Hint: think about Euclid's proof that there are infinitely many primes in* \mathbb{Z} .

You're doing great! :)
